

SnapBurst - Partner Collaboration Scenario

Status

EXTERNAL OVERVIEW

Purpose

This document describes one possible collaboration between SnapBurst and a partner company.

It is an optional partnership opportunity, not a change to SnapBurst's core product position or existing technical claim boundary.

The collaboration proposition

Many UAS companies concentrate on the physical aircraft:

- airframe;
- propulsion;
- flight controller;
- communications hardware;
- sensors;
- payloads.

SnapBurst concentrates on the governed decision and authority layer between mission autonomy and aircraft command execution.

The partner builds the body. SnapBurst provides the governed brain.

"Brain" in this context means deterministic command governance, authority control, communications-loss handling, recovery and evidence generation. It does not mean an LLM directly pilots the aircraft.

Possible partner

A suitable partner could be a company developing:

- an NDAA-compliant aircraft platform;
- a PX4-compatible airframe;
- communications or radio hardware;
- sensor or payload integration;
- a UAS intended for public-safety, infrastructure, agriculture or similar operations.

No specific partner is currently agreed.

Contribution split

Hardware partner

The partner would provide:

- aircraft or hardware platform;
- autopilot and flight-control interface;
- communications system;
- relevant sensors or payloads;
- platform-specific engineering support;
- access to hardware or flight-test activity.

SnapBurst

SnapBurst would provide:

- command-governance integration;
- pre-authorised operating-envelope enforcement;
- C2-loss and FreeFlight handling;
- governed recovery and handback;
- command and aircraft-lane attribution;
- structured decision and execution evidence.

Bounded demonstration scenario

A first collaboration should remain narrow and measurable.

Example:

- 1. Integrate SnapBurst with one partner aircraft or hardware-in-the-loop platform.
- 2. Run a normal mission segment with C2 available.
- 3. Introduce a controlled C2 interruption.
- 4. Confirm that the mission continues only within the authorised envelope.
- 5. Restore communications.
- 6. Confirm governed handback.
- 7. Produce a correlated evidence package showing the command source, governance verdicts, state transitions and aircraft response.

Intended outcome

The collaboration would demonstrate that:

- the partner's aircraft provides the physical operating platform;
- SnapBurst adds governed autonomy and evidence without replacing the autopilot;
- the combined system can be tested against a clear communications-loss scenario;
- both companies leave the collaboration with stronger technical and commercial evidence than either could produce alone.

Current claim boundary

The existing SnapBurst evidence is software-in-the-loop.

This proposed partner collaboration is not currently implemented, agreed with a partner or physically flight-validated.

It must not be presented as:

- an existing hardware integration;
- a confirmed partnership;
- certified BVLOS capability;
- completed physical-flight evidence;
- an LLM-controlled aircraft system.

Collaboration value

A suitable partner collaboration could define the integration boundary and support a credible route from the existing SnapBurst SITL evidence into hardware-in-the-loop or controlled-flight validation.
